

SOLAR SYSTEM SIMULATION

OPENGL & C++

Helena Moreno Chacón

Final Project - Solar System Simulation

This is a simulation of a "interior" Solar System based on OpenGL and C++.

I have programmed it under Mac OS, using XCode as development tool. Due it, I did not use some libraries as "glaux.h" and "window.h" (included in Windows OS), and the headers of the libraries are written with other path, for example:

```
#include <OpenGL/gl.h>    // Header File For The OpenGL32 Library
```

It works as fine as under Windows. But if you want to use the code on Windows, to have to change the path of the libraries.

In my simulation I have included the following objects:

- **The Sun**
- **4 planets around Sun:** Mercury, Venus, Earth and Mars.
- **3 satellites** around theirs planets: the Moon (around Earth), Deimos and Fobos (around Mars).
- **A "comet":** using particles.
- **The dotted "orbit"** of each planet. It is not necessary, but I used it to make proves.
- **The background** of the galaxy.

I calculated approximately the size of each planet and their distance to Sun using data from astronomical web pages.

Also I have programmed the following behaviors:

- **Illumination:** It becomes from a point immediately in front of Sun, and illuminates all objects. I put some red color in the light, to makes it more realistic.
- Each object has its own **texture**: I downloaded all textures from Sun, planets and satellites from <http://planetpixelemporium.com/earth.html>
- Each planet has its own **duration of year** (translation around Sun).
- Each planet has its own **duration of day** (rotation on its axis): Venus is the one planet that rotates in the opposite way of the others planets, so I changed its rotation velocity (slower) to appreciate it.
- The **particles** of the queue 's comet has its own behavior, and all the information of each one is stored in a array of structures of particles.

I calculated approximately each "planet year" and "planet day" using data from astronomical web pages.

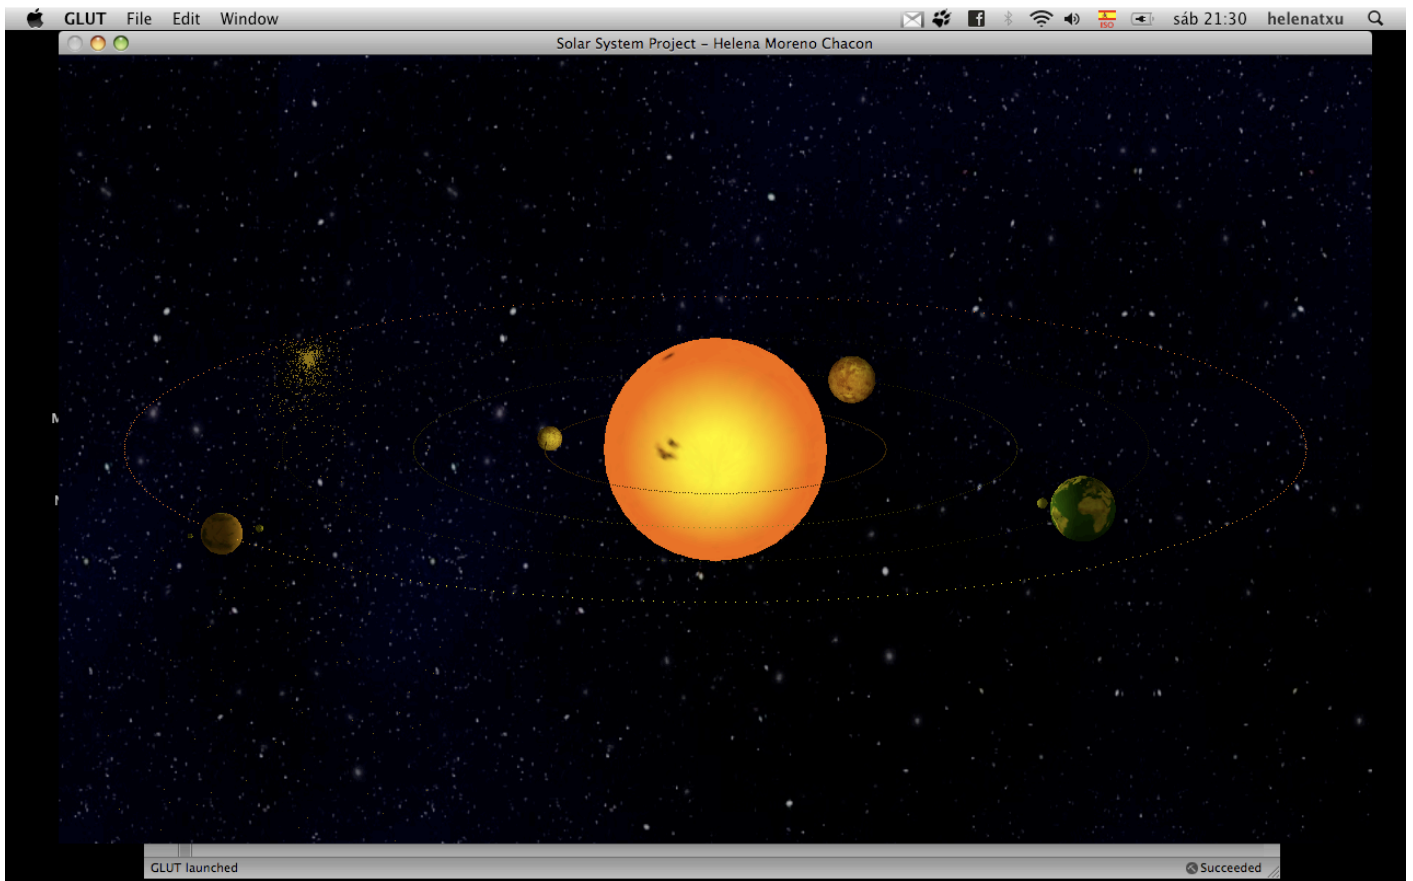

Animation Control: you can control the animation speed pressing the keys "Up" and "Down" during the animation.

Background of the galaxy: I add a texture with stars and I moved one light to the background to illuminate it.

Screen Shots:

- The First Screenshot (on the first page) was taken few moments after the animation start.
- The Second, Third and Fourth Screenshot were taken some seconds after the animation start.

(Continues in the next page...)
